Chapter 11: Linked lists

Section 11.1: A doubly linked list

An example of code showing how nodes can be inserted at a doubly linked list, how the list can easily be reversed, and how it can be printed in reverse.

```
#include <stdio.h>
#include <stdlib.h>
/* This data is not always stored in a structure, but it is sometimes for ease of use */
 /* Sometimes a key is also stored and used in the functions */
 int data;
 struct Node* next;
 struct Node* previous;
};
void insert_at_beginning(struct Node **pheadNode, int value);
void insert_at_end(struct Node **pheadNode, int value);
void print_list(struct Node *headNode);
void print_list_backwards(struct Node *headNode);
void free_list(struct Node *headNode);
int main(void) {
 /* Sometimes in a doubly linked list the last node is also stored */
 struct Node *head = NULL;
 printf("Insert a node at the beginning of the list.\n");
 insert_at_beginning(&head, 5);
 print_list(head);
 printf("Insert a node at the beginning, and then print the list backwards\n");
 insert_at_beginning(&head, 10);
 print_list_backwards(head);
 printf("Insert a node at the end, and then print the list forwards.\n");
 insert_at_end(&head, 15);
 print_list(head);
 free_list(head);
  return 0;
}
void print_list_backwards(struct Node *headNode) {
  if (NULL == headNode)
  {
    return;
 }
 Iterate through the list, and once we get to the end, iterate backwards to print
 out the items in reverse order (this is done with the pointer to the previous node).
 This can be done even more easily if a pointer to the last node is stored.
 struct Node *i = headNode;
 while (i->next != NULL) {
```

```
i = i->next; /* Move to the end of the list */
  }
 while (i != NULL) {
    printf("Value: %d\n", i->data);
    i = i->previous;
  }
}
void print_list(struct Node *headNode) {
  /* Iterate through the list and print out the data member of each node */
 struct Node *i;
  for (i = headNode; i != NULL; i = i->next) {
    printf("Value: %d\n", i->data);
}
void insert_at_beginning(struct Node **pheadNode, int value) {
 struct Node *currentNode;
 if (NULL == pheadNode)
    return;
  }
  /*
  This is done similarly to how we insert a node at the beginning of a singly linked
 list, instead we set the previous member of the structure as well
  */
 currentNode = malloc(sizeof *currentNode);
  currentNode->next = NULL;
  currentNode->previous = NULL;
  currentNode->data = value;
  if (*pheadNode == NULL) { /* The list is empty */
    *pheadNode = currentNode;
    return;
  }
  currentNode->next = *pheadNode;
  (*pheadNode)->previous = currentNode;
  *pheadNode = currentNode;
}
void insert_at_end(struct Node **pheadNode, int value) {
  struct Node *currentNode;
 if (NULL == pheadNode)
  {
    return;
  }
 This can, again be done easily by being able to have the previous element. It
 would also be even more useful to have a pointer to the last node, which is commonly
 used.
  */
  currentNode = malloc(sizeof *currentNode);
  struct Node *i = *pheadNode;
  currentNode->data = value;
```

```
currentNode->next = NULL;
  currentNode->previous = NULL;
  if (*pheadNode == NULL) {
    *pheadNode = currentNode;
    return:
  }
 while (i->next != NULL) { /* Go to the end of the list */
    i = i->next;
  i->next = currentNode;
  currentNode->previous = i;
void free_list(struct Node *node) {
 while (node != NULL) {
    struct Node *next = node->next;
    free(node);
    node = next;
  }
}
```

Note that sometimes, storing a pointer to the last node is useful (it is more efficient to simply be able to jump straight to the end of the list than to need to iterate through to the end):

```
struct Node *lastNode = NULL;
```

In which case, updating it upon changes to the list is needed.

Sometimes, a key is also used to identify elements. It is simply a member of the Node structure:

```
struct Node {
  int data;
  int key;
  struct Node* next;
  struct Node* previous;
};
```

The key is then used when any tasks are performed on a specific element, like deleting elements.

Section 11.2: Reversing a linked list

You can also perform this task recursively, but I have chosen in this example to use an iterative approach. This task is useful if you are inserting all of your nodes at the beginning of a linked list. Here is an example:

```
#include <stdio.h>
#include <stdlib.h>

#define NUM_ITEMS 10

struct Node {
  int data;
   struct Node *next;
};

void insert_node(struct Node **headNode, int nodeValue, int position);
void print_list(struct Node *headNode);
```

```
void reverse_list(struct Node **headNode);
int main(void) {
 int i;
 struct Node *head = NULL;
 for(i = 1; i <= NUM_ITEMS; i++) {</pre>
    insert_node(&head, i, i);
 print_list(head);
 printf("I will now reverse the linked list\n");
 reverse_list(&head);
 print_list(head);
  return 0;
}
void print_list(struct Node *headNode) {
 struct Node *iterator;
 for(iterator = headNode; iterator != NULL; iterator = iterator->next) {
    printf("Value: %d\n", iterator->data);
  }
}
void insert_node(struct Node **headNode, int nodeValue, int position) {
 int i;
 struct Node *currentNode = (struct Node *)malloc(sizeof(struct Node));
 struct Node *nodeBeforePosition = *headNode;
 currentNode->data = nodeValue;
 if(position == 1) {
    currentNode->next = *headNode;
    *headNode = currentNode;
    return;
  }
 for (i = 0; i < position - 2; i++) {
    nodeBeforePosition = nodeBeforePosition->next;
  }
  currentNode->next = nodeBeforePosition->next;
 nodeBeforePosition->next = currentNode;
void reverse_list(struct Node **headNode) {
 struct Node *iterator = *headNode;
 struct Node *previousNode = NULL;
 struct Node *nextNode = NULL;
 while (iterator != NULL) {
    nextNode = iterator->next;
    iterator->next = previousNode;
    previousNode = iterator;
    iterator = nextNode;
  }
 /* Iterator will be NULL by the end, so the last node will be stored in
 previousNode. We will set the last node to be the headNode */
  *headNode = previousNode;
```

}

Explanation for the Reverse List Method

We start the previousNode out as NULL, since we know on the first iteration of the loop, if we are looking for the node before the first head node, it will be NULL. The first node will become the last node in the list, and the next variable should naturally be NULL.

Basically, the concept of reversing the linked list here is that we actually reverse the links themselves. Each node's next member will become the node before it, like so:

```
Head -> 1 -> 2 -> 3 -> 4 -> 5
```

Where each number represents a node. This list would become:

```
1 <- 2 <- 3 <- 4 <- 5 <- Head
```

Finally, the head should point to the 5th node instead, and each node should point to the node previous of it.

Node 1 should point to NULL since there was nothing before it. Node 2 should point to node 1, node 3 should point to node 2, et cetera.

However, there is *one small problem* with this method. If we break the link to the next node and change it to the previous node, we will not be able to traverse to the next node in the list since the link to it is gone.

The solution to this problem is to simply store the next element in a variable (nextNode) before changing the link.

Section 11.3: Inserting a node at the nth position

So far, we have looked at inserting a node at the beginning of a singly linked list. However, most of the times you will want to be able to insert nodes elsewhere as well. The code written below shows how it is possible to write an insert () function to insert nodes *anywhere* in the linked lists.

```
#include <stdio.h>
#include <stdlib.h>
struct Node {
 int data;
 struct Node* next;
};
struct Node* insert(struct Node* head, int value, size_t position);
void print_list (struct Node* head);
int main(int argc, char *argv[]) {
 struct Node *head = NULL; /* Initialize the list to be empty */
 /* Insert nodes at positions with values: */
 head = insert(head, 1, 0);
 head = insert(head, 100, 1);
 head = insert(head, 21, 2);
 head = insert(head, 2, 3);
 head = insert(head, 5, 4);
 head = insert(head, 42, 2);
 print_list(head);
  return 0;
```

```
struct Node* insert(struct Node* head, int value, size_t position) {
  size_t i = 0;
  struct Node *currentNode:
  /* Create our node */
 currentNode = malloc(sizeof *currentNode);
  /* Check for success of malloc() here! */
  /* Assign data */
 currentNode->data = value;
  /* Holds a pointer to the 'next' field that we have to link to the new node.
     By initializing it to &head we handle the case of insertion at the beginning. */
  struct Node **nextForPosition = &head;
  /* Iterate to get the 'next' field we are looking for.
     Note: Insert at the end if position is larger than current number of elements. */
  for (i = 0; i < position && *nextForPosition != NULL; i++) {</pre>
      /* nextForPosition is pointing to the 'next' field of the node.
         So *nextForPosition is a pointer to the next node.
         Update it with a pointer to the 'next' field of the next node. */
      nextForPosition = &(*nextForPosition)->next;
  }
  /* Here, we are taking the link to the next node (the one our newly inserted node should
 point to) by dereferencing nextForPosition, which points to the 'next' field of the node
  that is in the position we want to insert our node at.
 We assign this link to our next value. */
  currentNode->next = *nextForPosition;
  /* Now, we want to correct the link of the node before the position of our
 new node: it will be changed to be a pointer to our new node. */
  *nextForPosition = currentNode;
  return head;
}
void print_list (struct Node* head) {
  /* Go through the list of nodes and print out the data in each node */
  struct Node* i = head;
 while (i != NULL) {
    printf("%d\n", i->data);
    i = i->next;
  }
}
```

Section 11.4: Inserting a node at the beginning of a singly linked list

The code below will prompt for numbers and continue to add them to the beginning of a linked list.

```
/* This program will demonstrate inserting a node at the beginning of a linked list */
#include <stdio.h>
#include <stdlib.h>

struct Node {
  int data;
  struct Node* next;
};
```

```
void insert_node (struct Node **head, int nodeValue);
void print_list (struct Node *head);
int main(int argc, char *argv[]) {
 struct Node* headNode;
 headNode = NULL; /* Initialize our first node pointer to be NULL. */
 size_t listSize, i;
 do {
    printf("How many numbers would you like to input?\n");
  } while(1 != scanf("%zu", &listSize));
 for (i = 0; i < listSize; i++) {
    int numToAdd;
    do {
      printf("Enter a number:\n");
    } while (1 != scanf("%d", &numToAdd));
    insert_node (&headNode, numToAdd);
    printf("Current list after your inserted node: \n");
    print_list(headNode);
  return 0;
}
void print_list (struct Node *head) {
 struct node* currentNode = head;
 /* Iterate through each link. */
 while (currentNode != NULL) {
      printf("Value: %d\n", currentNode->data);
      currentNode = currentNode -> next;
  }
}
void insert_node (struct Node **head, int nodeValue) {
 struct Node *currentNode = malloc(sizeof *currentNode);
 currentNode->data = nodeValue;
 currentNode->next = (*head);
  *head = currentNode;
}
```

Explanation for the Insertion of Nodes

In order to understand how we add nodes at the beginning, let's take a look at possible scenarios:

1. The list is empty, so we need to add a new node. In which case, our memory looks like this where HEAD is a pointer to the first node:

```
| HEAD | --> NULL
```

The line currentNode->next = *headNode; will assign the value of currentNode->next to be NULL since headNode originally starts out at a value of NULL.

Now, we want to set our head node pointer to point to our current node.

```
|HEAD | --> |CURRENTNODE| --> NULL /* The head node points to the current node */
```

This is done with *headNode = currentNode;

2. The list is already populated; we need to add a new node to the beginning. For the sake of simplicity, let's start out with 1 node:

```
HEAD --> FIRST NODE --> NULL
```

With currentNode->next = *headNode, the data structure looks like this:

```
currentNode --> HEAD --> POINTER TO FIRST NODE --> NULL
```

Which, obviously needs to be altered since *headNode should point to currentNode.

```
HEAD -> currentNode --> NODE -> NULL
```

This is done with *headNode = currentNode;

Chapter 12: Enumerations

Section 12.1: Simple Enumeration

An enumeration is a user-defined data type consists of integral constants and each integral constant is given a name. Keyword **enum** is used to define enumerated data type.

If you use **enum** instead of **int** or string/ **char***, you increase compile-time checking and avoid errors from passing in invalid constants, and you document which values are legal to use.

Example 1

```
enum color{ RED, GREEN, BLUE };

void printColor(enum color chosenColor)
{
    const char *color_name = "Invalid color";
    switch (chosenColor)
    {
        case RED:
            color_name = "RED";
            break;

        case GREEN:
        color_name = "GREEN";
        break;

    case BLUE:
        color_name = "BLUE";
        break;
}

printf("%s\n", color_name);
}
```

With a main function defined as follows (for example):

```
int main() {
    enum color chosenColor;
    printf("Enter a number between 0 and 2");
    scanf("%d", (int*)&chosenColor);
    printColor(chosenColor);
    return 0;
}
```

Example 2

(This example uses designated initializers which are standardized since C99.)

```
enum week{ MON, TUE, WED, THU, FRI, SAT, SUN };

static const char* const dow[] = {
   [MON] = "Mon", [TUE] = "Tue", [WED] = "Wed",
   [THU] = "Thu", [FRI] = "Fri", [SAT] = "Sat", [SUN] = "Sun" };

void printDayOfWeek(enum week day)
{
   printf("%s\n", dow[day]);
}
```

The same example using range checking:

```
enum week{ DOW_INVALID = -1,
    MON, TUE, WED, THU, FRI, SAT, SUN,
    DOW_MAX };

static const char* const dow[] = {
    [MON] = "Mon", [TUE] = "Tue", [WED] = "Wed",
    [THU] = "Thu", [FRI] = "Fri", [SAT] = "Sat", [SUN] = "Sun" };

void printDayOfWeek(enum week day)
{
    assert(day > DOW_INVALID && day < DOW_MAX);
    printf("%s\n", dow[day]);
}</pre>
```

Section 12.2: enumeration constant without typename

Enumeration types can also be declared without giving them a name:

```
enum { buffersize = 256, };
static unsigned char buffer [buffersize] = { 0 };
```

This enables us to define compile time constants of type int that can as in this example be used as array length.

Section 12.3: Enumeration with duplicate value

An enumerations value in no way needs to be unique:

```
#include <stdlib.h> /* for EXIT_SUCCESS */
#include <stdio.h> /* for printf() */
enum Dupes
{
   Base, /* Takes 0 */
   One, /* Takes Base + 1 */
   Two, /* Takes One + 1 */
   Negative = -1,
   AnotherZero /* Takes Negative + 1 == 0, sigh */
};
int main(void)
 printf("Base = %d\n", Base);
 printf("One = %d\n", One);
 printf("Two = %d\n", Two);
  printf("Negative = %d\n", Negative);
 printf("AnotherZero = %d\n", AnotherZero);
  return EXIT_SUCCESS;
}
```

The sample prints:

```
Base = 0
One = 1
Two = 2
```
